Abstract—The high-order symplectic finite-difference time-domain scheme is applied to modeling and simulation of waveguide structures. First, the perfect electric conductor boundary is treated by the image theory. Second, to excite all possible modes, an efficient source excitation method is proposed. Third, the modified perfectly matched layer is extended to its high-order form for absorbing the evanescent waves. Finally, a high-order scattering parameter extraction technique is developed. The cases of waveguide resonator, waveguide discontinuities, and periodic waveguide structure demonstrate that the high-order symplectic finite-difference time-domain scheme can obtain better numerical results than the traditional finite-difference time-domain method and save computer resources.

1. INTRODUCTION

As the most standard algorithm, the traditional finite-difference time-domain (FDTD) method [1, 2], which is explicit and second-order accurate in both space and time, has been widely applied to modeling and simulation of waveguide structures [3–11]. However, the numerical dispersion in the traditional FDTD method leads to less efficiency for solving the closed problems. Furthermore, waveguide simulations always consume longer CPU time compared with the same-sized scattering problems. Hence, the numerical results by the traditional FDTD method will suffer from significant accumulated errors.

To reduce the numerical dispersion in the traditional FDTD method, a variety of spatial high-order approaches, such as high-order FDTD [12, 13], multi-resolution time-domain [14, 15], and discrete singular convolution [16] methods, are proposed and their applications in waveguide simulation are developed. For the high-order approaches, there are still some problems left to be solved. On the one hand, the image theory uses the stair-cased model, which is inaccurate for treating the curved dielectric and conducting boundaries. On the other hand, the required high-order techniques for source excitation, absorbing boundary condition, and wide-band scattering parameter extraction are seldom reported.

Focusing on these points, we apply the high-order symplectic finite-difference time-domain (SFDTD) scheme to analyze the three-dimensional guided-wave problems. For the time direction, different from the five-stage fourth-order symplectic integrators used in [16, 17], the three-stage third-order symplectic integrators [18] are employed to achieve lower computational complexity. For the spatial direction, the fourth-order staggered difference with Yee lattice is used. Moreover, the required high-order techniques matched the SFDTD(3,4) scheme are developed.

2. THEORY

2.1. Formulation

A function of space and time evaluated at a discrete point in the Cartesian lattice and at a discrete stage in the time step can be written as

$$F(x, y, z, t) = F^{n+l/m}\Big(i\Delta_x, j\Delta_y, k\Delta_z, (n + \tau_l)\Delta_t\Big) \qquad (1)$$

where Δ_x, Δ_y, and Δ_z are, respectively, the lattice space steps in the x, y, and z coordinate directions, Δ_t is the time step, i, j, k, n, l, and m are integers, $n + l/m$ denotes the lth stage after n time steps, m is

the total stage number, and τ_l is the fixed time with respect to the lth stage.

For the spatial direction, the explicit and fourth-order-accurate staggered difference in conjugation with the Yee lattice is used to discretize the first-order spatial derivative

$$
\left(\frac{\partial F^{n+l/m}}{\partial \delta}\right)_h \approx \frac{9}{8} \times \frac{F^{n+l/m}(h+1/2) - F^{n+l/m}(h-1/2)}{\Delta_\delta}
$$
$$
- \frac{1}{24} \times \frac{F^{n+l/m}(h+3/2) - F^{n+l/m}(h-3/2)}{\Delta_\delta} \quad (2)
$$

where $\delta = x, y, z$ and $h = i, j, k$.

For the time direction, Maxwell's equations in homogeneous, lossless, and sourceless media can be written as [17]

$$
\frac{\partial}{\partial t}\begin{pmatrix}\mathbf{H}\\ \mathbf{E}\end{pmatrix} = (U + V)\begin{pmatrix}\mathbf{H}\\ \mathbf{E}\end{pmatrix} \quad (3)
$$

$$
U = \begin{pmatrix}\{0\}_{3\times3} & -\mu^{-1}\Re_{3\times3}\\ \{0\}_{3\times3} & \{0\}_{3\times3}\end{pmatrix}, \quad V = \begin{pmatrix}\{0\}_{3\times3} & \{0\}_{3\times3}\\ \varepsilon^{-1}\Re_{3\times3} & \{0\}_{3\times3}\end{pmatrix} \quad (4)
$$

$$
\Re_{3\times3} = \begin{pmatrix} 0 & -\frac{\partial}{\partial z} & \frac{\partial}{\partial y}\\ \frac{\partial}{\partial z} & 0 & -\frac{\partial}{\partial x}\\ -\frac{\partial}{\partial y} & \frac{\partial}{\partial x} & 0 \end{pmatrix} \quad (5)
$$

where $\mathbf{H}$ is the vector magnetic field, $\mathbf{E}$ is the vector electric field, $\{0\}_{3\times3}$ is the 3×3 null matrix, $\Re$ is the three-dimensional curl operator, and ε and μ are the permittivity and permeability of the media.

Using the product of elementary symplectic mapping, the exact solution of (3) can be approximated by the m-stage p-th symplectic integration scheme [19]

$$
\exp\left[\Delta_t\left(U + V\right)\right] = \prod_{l=1}^{m}\exp(d_l\Delta_t V)\exp\left(c_l\Delta_t U\right) + O\left(\Delta_t^{p+1}\right)
$$
$$
\approx \prod_{l=1}^{m}\left(I + d_l\Delta_t V\right)\left(I + c_l\Delta_t U\right) \quad (6)
$$

where c_l and d_l are the symplectic integrators. To lower the computational complexity of the high-order SFDTD scheme, we use the three-stage third-order symmetric symplectic integrators [18]. The symplectic integrators satisfy the relation $d_l = c_{m-l+1}$, $1 \le l \le m$
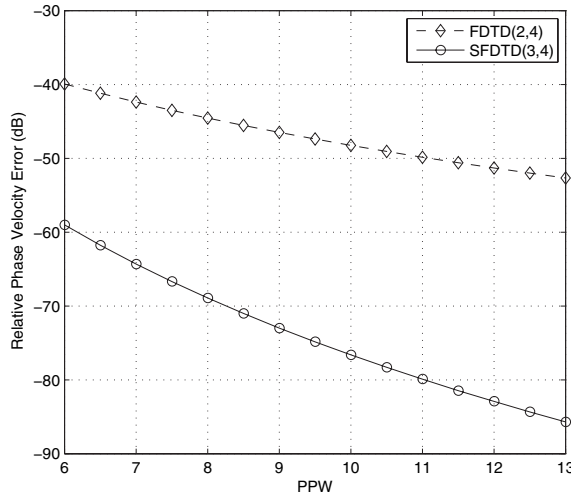

Figure 1. Dispersion curves for a plane wave traveling at $\theta = 60°$ and $\phi = 30°$ versus points per wavelength (PPW) discretization: CFL = 0.495.

with $m = 3$, $c_1 = 0.26833010$, $c_2 = -0.18799162$, and $c_3 = 0.91966152$. Compared with the Runge-Kutta method, the symplectic integration scheme can save considerable memory and conserves the symplectic structure of electromagnetic field [20].

As a result, the SFDTD(3,4) scheme is constructed. The Courant-Friedrichs-Levy (CFL) number of the SFDTD(3,4) scheme is 1.118, which is bigger than 0.743 for the SFDTD(4,4) scheme proposed in [17]. In each time step, the SFDTD(3,4) scheme only requires three stages compared with five stages for the SFDTD(4,4) scheme. Hence, considerable CPU time will be saved by the three-stage third-order symplectic integrators. Figure 1 gives the relative phase velocity error as a function of points per wavelength (PPW) for a plane wave traveling at $\theta = 60°$ and $\phi = 30°$. The CFL number is set to be 0.495 that is the stability limit of the FDTD(2,4) approach [13]. From Fig. 1, we can see that the SFDTD(3,4) scheme is superior to the FDTD(2,4) approach.

The update equation for the scaled electric field component ($\hat{E}_x =$

$\sqrt{\varepsilon_0/\mu_0}E_x)$ can be derived as follows

$$\hat{E}_x^{n+l/m}\left(i+\frac{1}{2},j,k\right) = \hat{E}_x^{n+(l-1)/m}\left(i+\frac{1}{2},j,k\right) + \frac{1}{\varepsilon_r\left(i+\frac{1}{2},j,k\right)}$$

$$\times\left\{+\alpha_{y1}\times\left[H_z^{n+l/m}\left(i+\frac{1}{2},j+\frac{1}{2},k\right)-H_z^{n+l/m}\left(i+\frac{1}{2},j-\frac{1}{2},k\right)\right]\right.$$

$$-\alpha_{z1}\times\left[H_y^{n+l/m}\left(i+\frac{1}{2},j,k+\frac{1}{2}\right)-H_y^{n+l/m}\left(i+\frac{1}{2},j,k-\frac{1}{2}\right)\right]$$

$$+\alpha_{y2}\times\left[H_z^{n+l/m}\left(i+\frac{1}{2},j+\frac{3}{2},k\right)-H_z^{n+l/m}\left(i+\frac{1}{2},j-\frac{3}{2},k\right)\right]$$

$$\left.-\alpha_{z2}\times\left[H_y^{n+l/m}\left(i+\frac{1}{2},j,k+\frac{3}{2}\right)-H_y^{n+l/m}\left(i+\frac{1}{2},j,k-\frac{3}{2}\right)\right]\right\} \quad (7)$$

$$\alpha_{y1} = \frac{9}{8}d_l\times\mathrm{CFL}_y,\ \ \alpha_{z1} = \frac{9}{8}d_l\times\mathrm{CFL}_z \quad (8a)$$

$$\alpha_{y2} = \frac{-1}{24}d_l\times\mathrm{CFL}_y,\ \ \alpha_{z2} = \frac{-1}{24}d_l\times\mathrm{CFL}_z \quad (8b)$$

$$\mathrm{CFL}_y = \frac{1}{\sqrt{\mu_0\varepsilon_0}}\frac{\Delta_t}{\Delta_y},\ \ \mathrm{CFL}_z = \frac{1}{\sqrt{\mu_0\varepsilon_0}}\frac{\Delta_t}{\Delta_z} \quad (9)$$

where ε_0 and μ_0 are the permittivity and permeability of free space, and ε_r is the relative permittivity of the media. For the uniform space step, $\Delta_x = \Delta_y = \Delta_z = \Delta_\delta$.

2.2. Boundary Treatment

Figure 2 shows a rectangular waveguide with size of $a \times b$. For the propagating modes, the electromagnetic waves travel along the z direction.

Figure 2. Geometry of a rectangular waveguide with size of $a \times b$.

Similar to the original operation [15, 16], the image theory is used for treating the perfect electric conductor boundary.

Take the conducting plane of $i = i_1$ for example, the tangential electric field components outside the waveguide are obtained by the anti-symmetric extensions

$$\hat{E}_y\left(i_1-1, j+\frac{1}{2}, k\right) = -\hat{E}_y\left(i_1+1, j+\frac{1}{2}, k\right), \ j_1 \le j \le j_2 - 1 \ (10)$$

$$\hat{E}_z\left(i_1-1, j, k+\frac{1}{2}\right) = -\hat{E}_z\left(i_1+1, j, k+\frac{1}{2}\right), \ j_1 \le j \le j_2 \quad (11)$$

Similarly, the tangential magnetic field components are obtained by the symmetric extensions

$$H_y\left(i_1-\frac{1}{2}, j, k+\frac{1}{2}\right) = H_y\left(i_1+\frac{1}{2}, j, k+\frac{1}{2}\right), \ j_1 \le j \le j_2 \quad (12)$$

$$H_y\left(i_1-\frac{3}{2}, j, k+\frac{1}{2}\right) = H_y\left(i_1+\frac{3}{2}, j, k+\frac{1}{2}\right), \ j_1 \le j \le j_2 \quad (13)$$

$$H_z\left(i_1-\frac{1}{2}, j+\frac{1}{2}, k\right) = H_z\left(i_1+\frac{1}{2}, j+\frac{1}{2}, k\right), \ j_1 \le j \le j_2 - 1 \ (14)$$

$$H_z\left(i_1-\frac{3}{2}, j+\frac{1}{2}, k\right) = H_z\left(i_1+\frac{3}{2}, j+\frac{1}{2}, k\right), \ j_1 \le j \le j_2 - 1 \ (15)$$

In addition, the high-order subcell strategy [21] is employed to model the material discontinuities. The strategy is compatible with the spatial fourth-order differences and can get the averaged permittivities at the dielectric-dielectric interface. The relevant theory and numerical results have been reported in [21].

2.3. Source Excitation

To excite the resonant modes, the initial conditions of the longitudinal fields are

$$H_z^0\left(i+\frac{1}{2}, j+\frac{1}{2}, k\right) = \exp\left[-\frac{\left(i+\frac{1}{2}-i_c\right)^2+\left(j+\frac{1}{2}-j_c\right)^2}{2\tau_g^2}\right] \quad (16)$$

$$\hat{E}_z^0\left(i, j, k+\frac{1}{2}\right) = \exp\left[-\frac{(i-i_c)^2+(j-j_c)^2}{2\tau_g^2}\right] \quad (17)$$

where i_c, j_c, and k_c are the grid indexes of waveguide center, and τ_g is the pulse width. To excite all possible modes, we take i, j, and k as $i_c \le i \le i_2$, $j_c \le j \le j_2$, and $k_c \le k \le k_2$.

To excite the propagating modes, the magnetic field source (electric current) and the electric field source (magnetic current) are respectively given by

$$\hat{E}_x^{n+l/m}\left(i+\frac{1}{2},j,k_s\right) = \hat{E}_x^{n+l/m}\left(i+\frac{1}{2},j,k_s\right)$$
$$+J_{inc}^{n+l/m}\left(i+\frac{1}{2},j,k_s-\frac{1}{2}\right) \quad (18)$$

$$H_y^{n+l/m}\left(i+\frac{1}{2},j,k_s-\frac{1}{2}\right) = H_y^{n+l/m}\left(i+\frac{1}{2},j,k_s-\frac{1}{2}\right)$$
$$+\hat{J}_{m,inc}^{n+(l-1)/m}\left(i+\frac{1}{2},j,k_s\right) \quad (19)$$

where $i_1 \leq i \leq i_2 - 1$, $j_1 \leq j \leq j_2$, and k_s is the source plane as shown in Fig. 3. In previous work, the magnetic field source was used extensively. Although the magnetic field source can excite the dominant TE_{10} mode, it can not excite some TM modes properly. Similarly, the electric field source can not excite the TE modes. Hence, we must employ (18) and (19) simultaneously.

Both the magnetic and electric field sources can be written as

$$\Pi(t,x,y) = \zeta(t) \cdot \vartheta(x,y), \ \Pi = J_{inc}, \hat{J}_{m,inc} \quad (20)$$

where $\zeta(t)$ is the cosine-modulated Gaussian pulse

$$\zeta(t) = -\cos(\omega t)\exp\left[-\frac{4\pi(t-T_0)^2}{W^2}\right] \quad (21)$$

Figure 3. The side view of the rectangular waveguide. The source excitation is added at the plane of $k = k_s$, and the scattering parameter ($\tilde{S}_{11}$ parameter) can be extracted at the plane of $k = k_r$. The first and second ends of the waveguide are the modified perfectly matched layer (MPML). The middle gray region denotes the discontinuities.

and its effective frequency range is $[\omega/2\pi - 2/W,\ \omega/2\pi + 2/W]$. The function $\vartheta(x,y)$ depends on the distribution of transverse fields, i.e.,

$$\vartheta(x,y) = \sum_m \sum_n \sin\left(\frac{m\pi y}{a}\right)\cos\left(\frac{n\pi x}{b}\right) \tag{22}$$

For the dominant TE_{10} mode, $m = 1$ and $n = 0$.

2.4. Modified Perfectly Matched Layer

In view of the spatial fourth-order differences used in the non-PML regions, the low-order perfectly matched layer (PML) using second-order differences will lead to the fictitious (non-physical) reflection at the media-layer interface. So, the modified perfectly matched layer (MPML) [22], which can absorb the evanescent waves, should be extended to its high-order form.

Using the split-field technique, the x component of the scaled electric field can be split into two subcomponents

$$\hat{E}_x = \hat{E}_{xy} + \hat{E}_{xz} \tag{23}$$

The update equation of the subcomponent $\hat{E}_{xy}$ can be given by

$$
\hat{E}_{xy}^{n+l/m}\left(i+\frac{1}{2},j,k\right) = \hat{E}_{xy}^{n+(l-1)/m}\left(i+\frac{1}{2},j,k\right) + \frac{1}{\varepsilon_r\left(i+\frac{1}{2},j,k\right)}
$$
$$
\times\left\{+\alpha_{y1}\times\left[H_z^{n+l/m}\left(i+\frac{1}{2},j+\frac{1}{2},k\right) - H_z^{n+l/m}\left(i+\frac{1}{2},j-\frac{1}{2},k\right)\right]\right.
$$
$$
\left. +\alpha_{y2}\times\left[H_z^{n+l/m}\left(i+\frac{1}{2},j+\frac{3}{2},k\right) - H_z^{n+l/m}\left(i+\frac{1}{2},j-\frac{3}{2},k\right)\right]\right\} \tag{24}
$$

One can see that there is no modified perfectly matched layer in the y direction. For the z direction, the update equation of the subcomponent $\hat{E}_{xz}$ is

$$
\hat{E}_{xz}^{n+l/m}\left(i+\frac{1}{2},j,k\right) = \exp\left(-\xi\right)\times\hat{E}_{xz}^{n+(l-1)/m}\left(i+\frac{1}{2},j,k\right)
$$
$$
+\frac{1-\exp\left(-\xi\right)}{\xi}\times\frac{1}{\varepsilon_{r,z}^p\left(i+\frac{1}{2},j,k\right)}\times\left\{-\alpha_{z1}\times\left[H_y^{n+l/m}\left(i+\frac{1}{2},j,k+\frac{1}{2}\right)\right.\right.
$$
$$
\left.-H_y^{n+l/m}\left(i+\frac{1}{2},j,k-\frac{1}{2}\right)\right] - \alpha_{z2}\times\left[H_y^{n+l/m}\left(i+\frac{1}{2},j,k+\frac{3}{2}\right)\right.
$$
$$
\left.\left.-H_y^{n+l/m}\left(i+\frac{1}{2},j,k-\frac{3}{2}\right)\right]\right\} \tag{25}
$$

where $\xi = d_l \Delta_t \sigma_z^p(i + \frac{1}{2}, j, k) / \varepsilon_z^p(i + \frac{1}{2}, j, k)$ and $\varepsilon_z^p = \varepsilon_0 \varepsilon_{r,z}^p$.

The electric conductivities and the relative permittivities in the modified perfectly matched layer can be set as

$$\sigma_z^p(\Lambda) = \sigma_{z\,\mathrm{max}}^p \left(\frac{\Lambda}{\Gamma} \right)^\kappa \tag{26}$$

$$\varepsilon_{r,z}^p(\Lambda) = \varepsilon_r \cdot \left[1 + \varepsilon_{r,z\,\mathrm{max}}^p \left(\frac{\Lambda}{\Gamma} \right)^\kappa \right] \tag{27}$$

where Γ is the layer thickness, Λ is the distance from the media-layer interface, and κ is the polynomial order. According to our numerical results, $\kappa = 3$ can achieve the best absorbing effect. The maximum of the electric conductivities is given by

$$\sigma_{z\,\mathrm{max}}^p = \frac{5 \times 10^{-4}}{\sqrt{\mu_r \varepsilon_r} \Delta_z} \tag{28}$$

and that of the relative permittivities is given by $5 \leq \varepsilon_{r,z\,\mathrm{max}}^p \leq 10$. In addition, (26) and (27) also suit the settings of the magnetic conductivities and the relative permeabilities in the modified perfectly matched layer.

2.5. Parameter Extraction

For the eigenvalue analysis of waveguide, one can find the cut-off and resonant frequencies by computing the total energy of the electric field in frequency-domain. For the cut-off frequency analysis, the waveguide is truncated by the modified perfectly matched layer and the total energy is of form

$$\Sigma_{\tilde{\mathbf{E}}}^S = \frac{1}{4} \iint_S \varepsilon \tilde{\mathbf{E}} \cdot \tilde{\mathbf{E}}^\dagger dS = \frac{1}{4} \iint_S \varepsilon \left(\left| \tilde{E}_x \right|^2 + \left| \tilde{E}_y \right|^2 + \left| \tilde{E}_z \right|^2 \right) dS \tag{29}$$

where $\tilde{\mathbf{E}}$ is the electric field in frequency-domain that can be obtained by the fast Fourier transform and S denotes the arbitrary transverse plane of the waveguide.

For the resonant frequency analysis, there is no absorbing boundary condition and the total energy for the waveguide resonator is

$$\Sigma_{\tilde{\mathbf{E}}}^V = \frac{1}{4} \iiint_V \varepsilon \tilde{\mathbf{E}} \cdot \tilde{\mathbf{E}}^\dagger dV = \frac{1}{4} \iiint_V \varepsilon \left(\left| \tilde{E}_x \right|^2 + \left| \tilde{E}_y \right|^2 + \left| \tilde{E}_z \right|^2 \right) dV \tag{30}$$

where V denotes the whole volume of the waveguide resonator.

For the computation of wide-band scattering parameter, the mode voltage and current can be defined as

$$\tilde{V} = \iint_S \left[\tilde{\mathbf{E}}_t(x, y, z_r) \times \tilde{\mathbf{h}}_{t,n}(x, y) \right] \cdot d\mathbf{S} \tag{31}$$

$$\tilde{I} = \iint_S \left[\tilde{\mathbf{e}}_{t,n}(x, y) \times \tilde{\mathbf{H}}_t(x, y, z_r) \right] \cdot d\mathbf{S} \tag{32}$$

where $\tilde{\mathbf{E}}_t$ and $\tilde{\mathbf{H}}_t$ are the transverse components of the electric and magnetic fields, $\tilde{\mathbf{e}}_{t,n}$ and $\tilde{\mathbf{h}}_{t,n}$ are the normalized transverse-field components of the nth eigenfunction, and $z_r = k_r \Delta_z$ is the z coordinate of the scattering parameter extraction plane.

Using the differential method [11], the characteristic impedance of the waveguide can be defined as

$$\tilde{Z} = \sqrt{\frac{\tilde{V} \cdot \left(d\tilde{V}/dz \right)}{\tilde{I} \cdot \left(d\tilde{I}/dz \right)}} \tag{33}$$

To obtain the high-order accuracy, the variables of (33) can be discretized as follows

$$\tilde{V}\bigg|_{z=z_r} = \tilde{V}(k_r) \tag{34}$$

$$\tilde{I}\bigg|_{z=z_r} \approx \frac{9}{16} \times \left[\tilde{I}(k_r + 0.5) + \tilde{I}(k_r - 0.5) \right]$$
$$- \frac{1}{16} \times \left[\tilde{I}(k_r + 1.5) + \tilde{I}(k_r - 1.5) \right] \tag{35}$$

$$\frac{d\tilde{V}}{dz}\bigg|_{z=z_r} \approx \frac{2}{3} \times \frac{\tilde{V}(k_r + 1) - \tilde{V}(k_r - 1)}{\Delta_z}$$
$$- \frac{1}{12} \times \frac{\tilde{V}(k_r + 2) - \tilde{V}(k_r - 2)}{\Delta_z} \tag{36}$$

$$\frac{d\tilde{I}}{dz}\bigg|_{z=z_r} \approx \frac{9}{8} \times \frac{\tilde{I}(k_r + 0.5) - \tilde{I}(k_r - 0.5)}{\Delta_z}$$
$$- \frac{1}{24} \times \frac{\tilde{I}(k_r + 1.5) - \tilde{I}(k_r - 1.5)}{\Delta_z} \tag{37}$$

Based on the transmission line theory, the incident and reflection

waves are of the form

$$\tilde{V}_{inc} = \frac{\tilde{V} + \tilde{Z} \cdot \tilde{I}}{2\sqrt{\tilde{Z}}} \tag{38}$$

$$\tilde{V}_{ref} = \frac{\tilde{V} - \tilde{Z} \cdot \tilde{I}}{2\sqrt{\tilde{Z}}} \tag{39}$$

Hence, the reflection coefficient or $\tilde{S}_{11}$ parameter can be obtained by

$$\tilde{S}_{11} = \frac{\tilde{V}_{ref}}{\tilde{V}_{inc}} \tag{40}$$

3. NUMERICAL RESULTS

1. The resonant frequency analysis for rectangular waveguide cavity. The size of the waveguide resonator is $a \times b \times c = 19.050\,\text{mm} \times 9.525\,\text{mm} \times 14.288\,\text{mm}$. Other parameters are taken as $\Delta_\delta = 2.381\,\text{mm}$, $\text{CFL}_\delta = 0.4$, and $n_{\max} = 10000$. The frequency of the cosine-modulated Gaussian pulse ranges form 12 GHz to 21 GHz. Within the frequency range, all possible resonant modes include TE_{101}, $\text{TE}_{110}(\text{TM}_{110})$, TE_{011}, and $\text{TE}_{111}(\text{TM}_{111})$. In particular, the

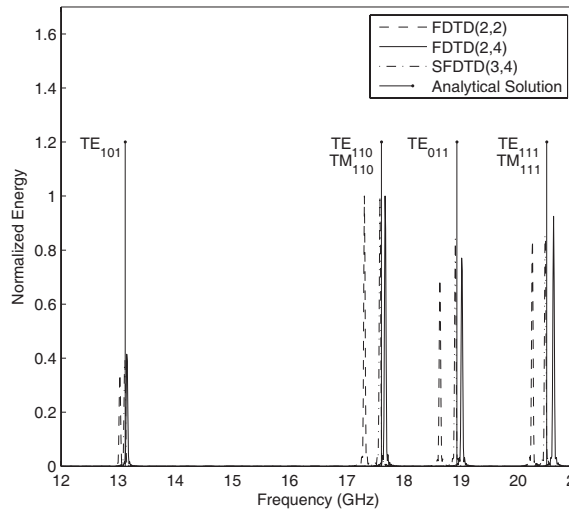

Figure 4. The resonant frequencies of the rectangular waveguide cavity.

perfect electric conductor boundary is treated by the image theory for the SFDTD(3,4) scheme. Using (30), the total energy of electric field in frequency-domain is computed. Figure 4 shows the curve of the normalized total energy and its peaks corresponding to the resonant frequencies. One can see that compared with the high-order FDTD(2,4) approach [13] and the traditional FDTD(2,2) method, the SFDTD(3,4) scheme can find the resonant frequencies better.

2. The cut-off frequency and scattering parameter analyses for dielectric-loaded waveguide. The WR-3 waveguide with size of $0.8636\,\mathrm{mm} \times 0.4318\,\mathrm{mm}$ is considered.

First, the different source excitation methods are compared for the cut-off frequency analysis. The settings are given as $\Delta_\delta = 0.072\,\mathrm{mm}$ and $\mathrm{CFL}_\delta = 0.5$, and the total energy of electric field is calculated by (29). The frequency range of interest is $[170\,\mathrm{GHz}, 780\,\mathrm{GHz}]$. If $m \in [0, 2]$ and $n \in [0, 2]$, all possible propagating modes include TE_{10}, TE_{01}, TE_{20}, $\mathrm{TE}_{11}(\mathrm{TM}_{11})$, $\mathrm{TE}_{21}(\mathrm{TM}_{21})$, $\mathrm{TE}_{12}(\mathrm{TM}_{12})$, and $\mathrm{TE}_{22}(\mathrm{TM}_{22})$. The result only with the magnetic field source (18) is shown in Fig. 5, where TM_{11} and TM_{12} modes can not be excited properly. Likewise, the result only with the electric field source (19) is shown in Fig. 6, where TE_{10}, TE_{01}, and TE_{20} modes can not be excited. However, once the magnetic field source is combined with the electric field source, all possible modes can be well excited as shown in Fig. 7.

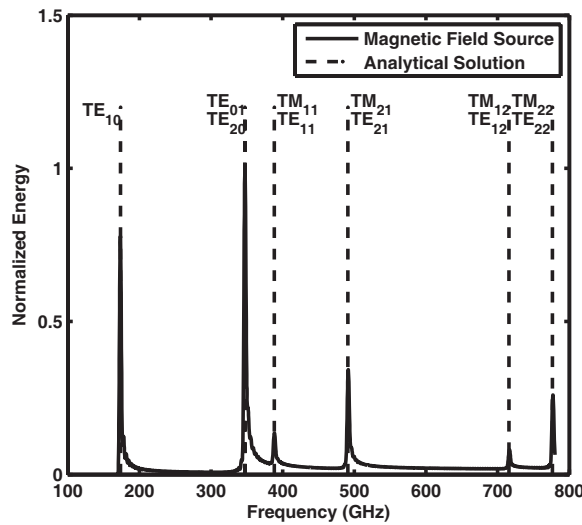

Figure 5. Magnetic field source excitation for computing the cut-off frequencies of the rectangular waveguide.

Second, we change the space step and the time step, then record the errors for the traditional FDTD(2,2) method and the SFDTD(3,4) scheme. The error can be defined as

$$\eta = \frac{\sum_{i=1}^{6} |f_i^{ana} - f_i^{num}|}{\max_i f_i^{ana}} \qquad (41)$$

where f_i^{ana} and f_i^{num} are the ith cut-off frequencies calculated by the analytical solution and the numerical method, respectively. From Table 1, for a given error bound 1%, the space step and the time

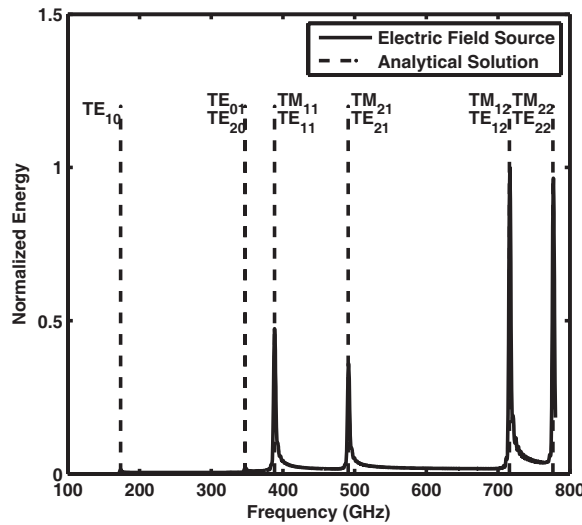

Figure 6. Electric field source excitation for computing the cut-off frequencies of the rectangular waveguide.

Table 1. The errors of the cut-off frequencies for the SFDTD(3,4) scheme and the traditional FDTD(2,2) method.

| Method	Δ_δ	CFL_δ	η
SFDTD(3,4)	0.072 mm	1.0	1.04%
SFDTD(3,4)	0.036 mm	1.0	0.19%
FDTD(2,2)	0.072 mm	0.5	6.61%
FDTD(2,2)	0.036 mm	0.5	1.43%

Figure 7. Combined field source excitation for computing the cut-off frequencies of the rectangular waveguide.

step of the SFDTD(3,4) scheme are two times bigger than those of the traditional FDTD(2,2) method. The memory of a time-domain algorithm is proportional to $O(1/\Delta_\delta^3)$. According to the computational complexity analysis in [18], the total simulation time is proportional to $O\big((1/\Delta_\delta^4) \cdot (m/CFL_\delta) \cdot (q)\big)$, where m is the stage number and q is the order of spatial difference. For the traditional FDTD(2,2) method, $m = 1$ and $q = 2$. For the SFDTD(3,4) scheme, $m = 3$ and $q = 4$. As a result, the ratio of memory cost for the traditional FDTD(2,2) method and the SFDTD(3,4) scheme is $8:1$. The ratio of CPU time for the traditional FDTD(2,2) method and the SFDTD(3,4) scheme is $16:3$.

Third, the local reflection coefficients for both the perfectly matched layer and the modified perfectly matched layer are analyzed. The $\varepsilon_{r,z\,\max}^p$ for the perfectly matched layer and the modified perfectly matched layer are, respectively, 0 and 5. The total computational region occupies $6 \times 12 \times 31$ grids and the record point is located at $(3, 6, 19)$. The number of the absorbing boundary layer is 10; the space step is $\Delta_\delta = 0.072\,\mathrm{mm}$; and the Courant-Friedrichs-Levy number is 1.0. To confirm the absorbing effect of the modified perfectly matched layer, the frequency range of Gaussian pulse is set to be $[170\,\mathrm{GHz}, 780\,\mathrm{GHz}]$. The numerical reference solution can be obtained if the number of longitudinal grids is so large that the propagating waves can not reach

the vacuum-layer interface. Moreover, the local reflection coefficients can be defined as

$$\rho(n) = 20 \log_{10} \frac{\left| \hat{E}_x^{Ref}(n) - \hat{E}_x^{Num}(n) \right|}{\max_n \left| \hat{E}_x^{Ref}(n) \right|} \tag{42}$$

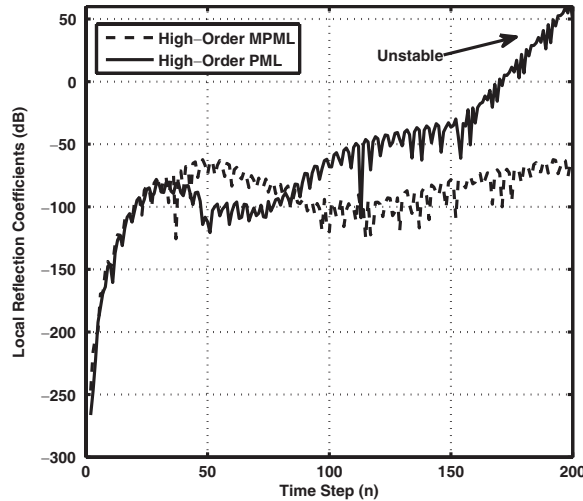

Figure 8. The local reflection coefficients of the high-order perfectly matched layer (PML) and the high-order modified perfectly matched layer (MPML).

where $\hat{E}_x^{Ref}$ and $\hat{E}_x^{Num}$ are, respectively, the reference and numerical solutions for the $\hat{E}_x$ field. Figure 8 shows the local reflection coefficients as a function of time step. Although both the perfectly matched layer and the modified perfectly matched layer employ the split-field forms and are weakly well-posed [23], the modified perfectly matched layer can keep stable as the time step increases. It is noted that two symplectic integrators c_2 and d_2 are negative, hence the exponential factor $\exp(-\xi)$ in (25) is expected to be bigger than 1. To achieve good absorbing effect, we can not decrease the conductivities drastically and therefore the exponential factor will become very large in some stages. Fortunately, the permittivities and permeabilities of the modified perfectly matched layer can also be large. Thus, the amplitude of the exponential factor will be damped. Based on the explanations, the modified perfectly matched layer is always more stable than the perfectly matched layer under the same absorbing effect condition. To

further test the stability of the modified perfectly matched layer, the program runs for 50000 time steps. We find the modified perfectly matched layer is still stable.

Finally, the waveguide discontinuities are simulated. Loaded with a dielectric square cylinder of relative permittivity 3.7 and of size $0.8636\,\mathrm{mm} \times 0.4318\,\mathrm{mm} \times 0.504\,\mathrm{mm}$, the waveguide is driven in the TE_{10} dominant-mode with frequency range of $[180\,\mathrm{GHz}, 340\,\mathrm{GHz}]$. The settings are taken as $\Delta_\delta = 0.056\,\mathrm{mm}$, $CFL_\delta = 0.5$, and $n_{\max} = 10000$. For the traditional FDTD(2,2) method, the air-dielectric interface is modeled by the low-order subcell strategy [24] and the scattering parameter is extracted by the low-order differential method [11]. For the SFDTD(3,4) scheme, both the high-order subcell strategy [21] and the high-order differential method are employed. From Fig. 9, it can be clearly seen that the scattering parameter computed by the SFDTD(3,4) scheme agrees with the reference solution well.

3. Computation of wide-band scattering parameter for periodic waveguide structure. Figure 10 shows the geometry of the structure. The space steps are set as $\Delta_x \times \Delta_y \times \Delta_z = 14.542\,\mathrm{mm} \times 4.847\,\mathrm{mm} \times 7.271\,\mathrm{mm}$, and the Courant-Friedrichs-Levy numbers are taken as 1.0 and 0.5 respectively for the SFDTD(3,4) scheme and the traditional FDTD(2,2) method. Within the frequency range of 2.7 GHz to 5.1 GHz, the waveguide works at the TE_{10} mode. For the SFDTD(3,4)
Figure 10. The geometry of the periodic waveguide structure. The size of the waveguide is $a \times b = 58.170 \, \text{mm} \times 29.083 \, \text{mm}$, and each dielectric cylinder with diameter of $b/2$, height of b, and relative permittivity of 2.1 is placed at an equidistance of b.

Figure 11. The scattering parameter of the periodic waveguide structure. The AM and LM in legend denote averaged material and local material, respectively.

scheme, the curved air-dielectric interface is treated by the local and averaged material models. The averaged material model uses the high-order subcell strategy [21]. For the traditional FDTD(2,2) method, the averaged material model uses the low-order subcell strategy [24]. Similar to the $\tilde{S}_{11}$ parameter, the $\tilde{S}_{21}$ parameter can be calculated by (38)–(40) but should be extracted at the right hand of the waveguide. From Fig. 11, one can see that the averaged material model is superior to the local material model. Furthermore, the result by the traditional FDTD(2,2) method loses some accuracy when the frequency increases. The infinity-norm errors for the averaged-material-SFDTD(3,4), local-material-SFDTD(3,4), and averaged-material-FDTD(2,2) methods are 0.73, 5.03, and 1.20. The two-norm errors for the three methods are 1.84, 12.13, and 2.81.

4. CONCLUSION

The SFDTD(3,4) scheme, which is explicit, non-dissipate, and high-order-accurate, has been introduced to simulate the three-dimensional waveguide problems. A variety of techniques involving boundary treatment, source excitation, absorbing boundary condition, and scattering parameter extraction are developed to match the scheme. First, the image theory and the high-order subcell strategy are used respectively to treat the perfect electric conductor boundary and the dielectric-dielectric interface. Second, to excite all possible propagating modes, the combined source excitation is required. Third, the modified perfectly matched layer has good absorbing effect and keeps stable for long-term simulation. Finally, the scattering parameter can be extracted by running program once and is still accurate under coarse grid condition. With the aid of the techniques, the high-order SFDTD scheme can achieve high accuracy and save computer resources.
